# Overview of EP Systems

- *Electrothermal*
  - propellant heated by electrical process & expanded through a nozzle
  - resistojets (hydrazine,  $I_{sp} \approx 300$  sec, 300 mN,  $\varepsilon \approx 80\%$ , 750 W)
  - arcjets (hydrazine,  $I_{sp} \approx 600$  sec, 250 mN,  $\varepsilon \approx 40\%$ , 1.5k W)
- *Electrostatic*
  - propellant accelerated by electrostatic forces to ionise particles
  - ion thruster (xenon,  $I_{sp} \approx 4000$  sec, 100 mN,  $\varepsilon \approx 65\%$ , 0.75 - 27 kW)
  - FEEP (cesium,  $I_{sp} \approx 10000$  sec, <5 mN,  $\varepsilon \approx 95\%$ ,  $\approx 500$ W)
- *Electromagnetic*
  - propellant accelerated by combined action of electric & magnetic fields
  - MPD/Li-LFA (lithium,  $I_{sp} \approx 4000$  sec, 12.5 N,  $\varepsilon \approx 48\%$ , 200 kW)
  - Hall thruster (xenon,  $I_{sp} \approx 1800$  sec, 80 mN,  $\varepsilon \approx 50\%$ , 200 kW)

# Station Keeping & Orbit Transfers

- Used on Russian satellites since 1970s
- > 150 EP systems have flown
- Applications
  - Attitude control
  - Station keeping
  - Drag reduction
  - Orbit changing functions
    - Gentle spiral trajectories
- Advantages
  - High precision thrust
  - Low propellant consumption
  - Long life

# Interplanetary Travel

- Deep Space 1 (Braille asteroid -1998)
  - ion thruster, 12kg Xe, 1800 hr thrust
- Hayabusa (Itokawa - 2003)
  - 4 ion thrusters, 22kg Xe, >26,000 hrs
- SMART-1 (Moon - 2003)
  - Hall thruster, 12kg Xe, 0.07 N, 1.5 year trip

<http://sp3.anu.edu.au>

# Interplanetary Travel

- DAWN (Ceres & Vesta - 2007)
  - 4 ion thrusters, 250kg Xe, 90mN, 6 yr trip
- BepiColombo (Mercury - 2013)
  - ion thruster, 0.24 N, 6 yr trip

# Dual-Stage 4 Grid (DS4G) Ion Thruster

- ESA test campaigns 2005 & 2006
  - 43 aperture grid
  - Max 30kV beam potential
  - Thrust = 2.7 mN
  - Isp = 14000 sec
- Total Power = 300 W
- Mass utilisation efficiency = 96%
- Total efficiency = 63%
- Thrust density = 0.86 nN/cm<sup>2</sup>
- Beam divergence = 4-6°

<http://sp3.anu.edu.au>

# Helicon Double Layer Thruster (HDLT)

- Magnetoplasmadynamic system
- Simple design – no moving parts
- Low thrust but scalable (~1-10mN)
- Propellants – H<sub>2</sub>, O<sub>2</sub>, Xe, Ar
- No electrodes or neutraliser needed
  - Long operating life
- High exhaust velocity > 10 km/sec
- $V_{\text{exhaust}} \sim 15 \text{ km/sec}$  with O<sub>2</sub>
- Beam divergence  $\sim 2^\circ$
- Scalable in size and power

# Helicon Double Layer Thruster (HDLT)

# Propulsion System Parameters

$$P_e = \frac{F_{\max} \cdot I_{sp}}{2 \cdot \eta_{th}}$$

where  $F_{\max}$  is maximum thrust level,  $I_{sp}$  is specific impulse,  $\eta_{th}$  is thruster efficiency and  $P_e$  is electrical input power

**For Mars missions  
optimum  $I_{sp} \sim 3000$  sec  
and thrust  $\sim 100$ N**

From Schmidt, T. D. & Auweter-Kurtz, M., 2005, 'Adequate electric propulsion system parameters for piloted Mars missions', IEPC-2005 Proceedings.

# Mars Mission Requirements

## *Crewed Missions*

- Fast transit times
- Numerous abort options
- Power for life support
- High system redundancy
- Reasonable acceleration
  - avoid van Allen belt radiation

## *Cargo Missions*

- High payload capacity
  - reduce propellant
- Transit time non critical
- Nominal power requirements
- Autonomous & limited complexity
- Reusable system

<http://sp3.anu.edu.au>

# Mission Scenarios

## *Traditional Direct NEP or SEP*

- Large vehicle constructed on orbit
  - separate nuclear reactor from crew
  - sufficient solar panel array
- Long spiral from LEO
- Continuous operation
  - long acceleration & deceleration
- Land & leave vehicle in Mars orbit
- Spiral (yet shorter) from Mars orbit

# Mission Scenarios

## *Hybrid SEP/Chemical*

- Cargo vehicle departs first
- 30-85 day spiral from LEO
- Crew follow in smaller vehicle
- Dock & proceed with either EP or chemical system
- Chemical system assists with Mars Orbit Insertion (MOI)

**OR**

- Cargo vehicle uses EP
- Crew vehicle use chemical

# Mars Mission Propulsion Options

Propulsion Option	Description	Advantages	Disadvantages
<i>Chemical</i>	Conventional cryogenic rocket engines, usually one stage per major maneuver (TMI, MOI & TEI). Insulated tanks with vapor-cooled shields to reduce boil off. Start T/W 0.1 to 0.25. $I_{sp} \sim 460s$ .	<ul style="list-style-type: none"> <li>• Mature technology</li> <li>• High thrust, short burn times</li> <li>• Ballistic interplanetary transfers facilitate implementing artificial gravity</li> </ul>	<ul style="list-style-type: none"> <li>• Low performance leads to high IMLEO except for conjunction profile with long transfer times</li> <li>• Cryogenic with <math>H_2</math>, low density, needs leak control</li> <li>• Expendable system</li> </ul>
<i>Chemical &amp; Aerocapture</i>	As above except aerocapture used for MOI. Large aeroshell needed requiring either intact launch or in-space assembly. Lander may capture separately to simplify configuration	<ul style="list-style-type: none"> <li>• Reduces IMLEO by replacing one major maneuver with aerocapture</li> </ul>	<ul style="list-style-type: none"> <li>• Performance still marginal for 'hard year' opportunities</li> <li>• Aerocapture risk: TPS/thermal, GN&amp;C</li> <li>• Expendable system</li> </ul>
<i>NTR</i>	Nuclear thermal rocket engine, $H_2$ propellant, $I_{sp} \sim 900s$ . Insulated tanks as above; start T/W $\leq 0.1$ to reduce nuclear engine size.	<ul style="list-style-type: none"> <li>• Known technology</li> <li>• Twice <math>I_{sp}</math> of chemical reduces IMLEO &amp; sensitivity to opportunity</li> <li>• High thrust, short burn times</li> <li>• Ballistic interplanetary transfers facilitate implementing artificial gravity</li> </ul>	<ul style="list-style-type: none"> <li>• Nuclear costs &amp; risks</li> <li>• Engine test protocols not resolved (containing radioactive products)</li> <li>• Cryogenic with <math>H_2</math>, low density, needs leak control (worse for <math>H_2</math>)</li> <li>• Expendable system</li> </ul>

From Griffin, B, et al, 2004, 'A Comparison of Transportation Systems for Human Missions to Mars', Proceedings of Joint Propulsion Conference 2004, AIAA 2004-3834.

# Mars Mission Propulsion Options

Propulsion Option	Description	Advantages	Disadvantages
<i>SEP</i>	Large (multi-MW) solar electric propulsion system, performs all major maneuvers. $I_{sp}$ typically 3000s; MPD or comparable thrusters.	<ul style="list-style-type: none"> <li>• Known technology with increasing flight experience</li> <li>• High <math>I_{sp}</math> reduces IMLEO &amp; sensitivity</li> <li>• No hydrogen propellant</li> <li>• <b>Reusable system</b></li> </ul>	<ul style="list-style-type: none"> <li>• Large size may require more space assembly</li> <li>• High power EP systems not mature (TRL 2-3)</li> <li>• Achievable power-to-mass ratios may exclude some opposition class profiles</li> </ul>
<i>NEP</i>	Large (multi-MW) nuclear electric propulsion system, probably Brayton or liquid metal Rankine power generation, performs all major maneuvers. $I_{sp}$ typically 3000s; MPD or comparable thrusters.	<ul style="list-style-type: none"> <li>• Known technology (no space experience &amp; few experimental prototypes)</li> <li>• High <math>I_{sp}</math> reduces IMLEO &amp; sensitivity</li> <li>• No hydrogen propellant</li> <li>• Potentially reusable system</li> </ul>	<ul style="list-style-type: none"> <li>• Nuclear costs &amp; risks</li> <li>• Large size may require more space assembly</li> <li>• High power EP systems not mature (TRL 2-3)</li> <li>• Achievable power-to-mass ratios may exclude some opposition class profiles</li> </ul>
<i>SEP &amp; Chemical</i>	Large SEP 'tug' system ~ 1 MW delivers chemical interplanetary vehicle to highly elliptical Earth orbit (perhaps in parts for assembly). Chemical propulsion system departs from this orbit & proceeds as chemical option.	<ul style="list-style-type: none"> <li>• <b>Placement in elliptic orbit reduces chemical <math>\Delta v \sim 3</math> km/s, reducing IMLEO &amp; sensitivity to opportunity</b></li> <li>• Same as chemical</li> <li>• SEP 'tug' is reusable</li> </ul>	<ul style="list-style-type: none"> <li>• Costs &amp; mission complexity added by use of SEP 'tug'</li> <li>• Cryogenic with <math>H_2</math>, low density, needs leak control</li> <li>• Chemical component is expendable system</li> </ul>

# Conclusions

- Electric propulsion is a maturing technology
- Australia is contributing to next generation EP system development
- The benefits of EP for Mars exploration warrant further research particularly in light of performance of next generation systems
  - desirable  $I_{sp}$  & thrust range
  - reduce propellant requirement & therefore reduce IMLEO
- Straight SEP or NEP systems are plausible (yet may not be practical)
- Hybrid approach may be the most appropriate - more studies needed
- Irrespective, lets get to Mars anyway!! :o)
